PROJECT PORTAL WORKFLOW MANAGEMENT

Concise Narrative Guide to Features and Lifecycle

A short, connected explanation of what the portal does, who uses it, and how work moves from the first bid or project entry to final client approval.

Feature-focused edition | Version 6.0

1. The Portal in One Story

Project Portal Workflow Management brings bids, projects, work requests, engineering activities, documents, approvals, revisions, and client communication into one connected workspace. A bid or project provides the main business context, while one or more work requests represent the actual deliverables that must be prepared, checked, approved, and sent to the client. Every action remains connected to the same record, so users can see what has happened, who is responsible now, and what must happen next.

The portal is role-based. Each person sees the records and actions relevant to their responsibility. A coordinator sees project and client-facing work, a division member sees assigned preparation tasks, a TMS checker sees packages waiting for checking, and a client sees only the records belonging to that client account. As work moves from one role to another, the status, assignment, history, documents, and notification all move together. This turns the portal into a controlled journey rather than a collection of separate screens.

The central idea

A bid or project holds the overall business record. Work requests carry the individual deliverables through preparation, engineering, review, delivery, revision, and acceptance.

2. The Roles and Their Place in the Journey

System Administration and Oversight

The System Administrator maintains the environment that supports the whole portal. This includes companies, divisions, teams, members, and the controlled options used in forms. The Prime Consultant has broad operational visibility across the same portfolio and can review bids, projects, work requests, documents, and progress from an overall management perspective. Together, these roles ensure that the portal structure matches the organization and that management can observe the complete workload.

CCR Coordinator / Marketing

CCR or Marketing begins and coordinates most business journeys. This role creates the bid or project, records client and project information, uploads the initial files, and creates work requests for the required deliverables. CCR selects the responsible division, provides instructions, supports internal information requests, reviews the final engineering package, and sends approved files to the client. When the client asks for a revision, CCR decides whether the issue should return to TMS Engineering or to the originating PMO or ECM division.

PMO / ECM Division Lead and Member

The Division Lead receives a new work request, confirms what is required, and assigns the appropriate Division Member. The member prepares the requested work, uploads files, raises questions when information is missing, and submits the package to the lead. The lead either approves the package for TMS or returns it for correction. This pair of roles provides the first internal preparation and quality-control stage.

TMS Engineering Roles

The TMS Manager organizes the engineering chain by assigning M1, M2, and M3 responsibilities. TMS-M1 prepares or revises the drawing, TMS-M2 performs checking, and TMS-M3 gives engineering approval. After these stages are completed, the TMS Manager or Engineering Lead performs the final release review and sends the package to CCR. If a correction is needed, the package returns to the correct earlier role instead of starting again as a separate record.

Client / Owner

The Client reviews the final package sent by CCR. The client can accept it, reject it, or request a revision with comments and supporting files. Acceptance completes the work request and records the final approved documents. A revision returns to CCR, which routes the correction through the correct internal path before the updated package is sent back to the client.

3. Dashboard: The Starting Point

The Dashboard gives every user a quick view of the work that matters to them. KPI cards show active projects, active bids, pending reviews, and approved documents. Quick Access opens the main workspaces, while Quick Actions allow authorized users to create a bid, project, or work request without navigating through several pages. Critical submissions highlight items that need attention, and the activity trail shows recent handoffs, approvals, rejections, and revisions.

The Dashboard changes with the role. A manager sees a broader portfolio, while an assigned member sees the requests waiting for personal action. This makes the page useful as both a management overview and a daily task workspace. Selecting an item opens the relevant bid, project, work request, or action interface so the user can continue immediately.

4. Bids and Projects: The Business Record

The Projects/Bids area stores the main commercial and operational records. Authorized users can create a bid or project, select the client, record ports, cargo, vessel, shipment, source, and other key details, upload intake documents, and generate the structured code and root folder used throughout the portal. Users can search and filter records, see progress and status, open details, review related work requests, and access the workflow attached to each record.

A bid remains connected to its work requests while the required deliverables are prepared and reviewed. When all related work is accepted and the commercial decision is positive, the bid can become an active project without losing its documents or history. A rejected bid moves to the archive and may later return for another client review when authorized. Projects remain active containers for additional work requests as new deliverables arise.

5. Work Requests: Where the Deliverable Moves

A work request turns a broad bid or project requirement into a specific piece of work. It records the title, type, priority, attachment category, responsible division, instructions, assignments, current status, related documents, and history. Because each work request moves independently, one deliverable may be complete while another is still being prepared or revised under the same parent project.

The available actions change with the current stage and role. A lead can assign a member, a member can submit prepared work, M1 can submit a drawing, M2 can approve or reject checking, M3 can approve or return the package, CCR can send the final package to the client, and the client can make the final decision. Users therefore see only the actions that are valid for them at that moment.

6. Documents: One History for Every File

The Documents area organizes files under bids and projects using a structured folder hierarchy. Users can move through root folders, document folders, date or revision folders, and individual files using breadcrumbs, search, grid view, or list view. Images, PDFs, and supported text files can be previewed, while other file types remain available for download.

Document names and folders are generated from project information such as the bidding number, project code, cargo code, vessel code, shipment number, document code, upload date, and revision code. When the same logical document is uploaded again, its version increases while earlier files remain available. Formal revision uploads are placed under the correct revision identity, allowing the final document to be traced back through every earlier submission.

7. Notifications, History, and Collaboration

Notifications guide users to the next required action. Assignments, submissions, information requests, approvals, rejections, client responses, and revision requests generate role-specific notifications. The unread count shows what is new, and selecting a notification opens the exact related record or action area. Users can mark individual messages or the full list as read without removing the underlying history.

The activity trail, transfer history, and revision history explain how the work reached its current position. They record who acted, what decision was made, where responsibility moved, and why a revision occurred. Information requests also remain inside the work request, allowing a member to ask a lead, a lead to ask CCR, CCR to ask the client, or a TMS member to ask the Engineering Lead. After the response is provided, the work returns to the stage where it paused.

8. Organization, Teams, and Settings

The Companies and Divisions area represents the organization inside the portal. Teams can be created under the correct company and division, with a lead and assigned members. Unassigned users remain visible so administrators can complete the structure. These records make it possible for the workflow to route work to the right group and person.

Settings maintain the reusable information used across the portal, including the portal name, ports, cargo and vessel codes, document names and codes, work-request types, project-information categories, and attachment categories. Keeping these values controlled makes forms consistent and supports reliable code, folder, and document generation.

9. The Complete Lifecycle

Beginning the work

The journey begins when CCR creates a bid or project and records the client and operational information. Initial documents are uploaded, and one or more work requests are created for the required deliverables. Each work request is sent to the appropriate PMO or ECM division with its priority, instructions, category, and supporting files.

Preparation and internal review

The Division Lead reviews the request and assigns a Division Member. The member prepares the work and submits it for review. If the lead finds an issue, the request returns to the member with comments; if the package is acceptable, it moves to TMS. Missing information can be requested at any point, and the workflow resumes from the same stage after the answer is received.

Engineering drawing, checking, and approval

The TMS Manager assigns M1, M2, and M3. M1 prepares the drawing, M2 checks it, and M3 provides engineering approval. A rejection at M2 or M3 returns the package to M1, after which the revised drawing passes through checking and approval again. When all three stages are complete, the Engineering Lead performs the final release review and sends the latest engineering package to CCR.

Client delivery and decision

CCR reviews the package from a client-delivery perspective, selects the final files, and submits them to the Client. The Client may accept the package, reject it, or request a revision. Acceptance completes the work request and records the approved output. Rejection closes that deliverable while preserving its full history. A revision returns to CCR, which routes it to TMS or PMO/ECM depending on the nature of the change.

Revision and completion

A revision stays inside the same work request. The responsible role corrects the issue, uploads a new version, and sends the package through every required review stage again. This prevents a revised drawing or technical package from bypassing checking and approval. Once the latest package is accepted, the final documents remain stored under the parent bid or project. Projects can continue with additional work requests, while a successful bid can be converted into an active project with all connected records preserved.

Lifecycle in one sentence

Create the business record, divide the work into requests, prepare and review the deliverables, complete engineering approval, deliver to the client, revise when necessary, and preserve the accepted result with its full history.

10. The Overall Value

The portal gives every participant a shared understanding of the project journey. It shows what is being worked on, who is responsible, which document is current, what decision was made, and what must happen next. Features such as the Dashboard, work-request actions, document explorer, notifications, teams, and settings are valuable because they support this single connected flow.

For non-technical readers, the portal can be understood as a controlled conversation around each deliverable. CCR explains what is needed, PMO or ECM prepares the foundation, TMS turns it into checked and approved engineering output, CCR delivers it, and the Client makes the final decision. When work moves forward or backward, its files, comments, responsibilities, and history move with it. That continuity is the main purpose of Project Portal Workflow Management.
